

### Mechanical quantities 1/37 s07/4

- Temperature (NVE MD):  $T_{kin} = \frac{E_{kin}}{fk_B/2}$  notation here:  $U = U(r^N) =$  potential energy,  $E = E(T, V) =$  internal energy,  $f = \#$  of degrees of freedom
- Internal energy:  $E = (E_{kin} + U) \stackrel{NVT}{=} \frac{f}{2} k_B T + (U) \equiv E_{id} + E_{res}$  res = residual see next slide
- Pressure:  $p = \frac{N}{V} k_B T - \left\langle \left( \frac{\partial U(V^{1/3} \xi^N)}{\partial V} \right)_{\xi^N} \right\rangle \equiv p_{id} + p_{res}$   $\beta = 1/k_B T$

- dimensionless (scaled) coordinates  $\xi_i: r_i = V^{1/3} \xi_i$   
 - red derivative is calculated at constant  $\xi^N$   
 - whole configurations is uniformly shrank/swelled  
 -  $p_{id}$  = kinetic contribution (=ideal gas), also  $p_{id} = \phi 2E_{kin}/3V$ , where in periodic b.c.  $\phi = N/(N-1)$  takes into account 3 zero conserved momenta  
 -  $p_{res}$  = cohesion contribution

### Pressure tensor + 6/37 s07/4

Also called stress tensor (in solids):

$$\vec{P} = \vec{P}_{id} + \vec{P}_{res} = \frac{1}{V} \sum_{i=1}^N (\phi m_i \dot{v}_i \dot{v}_i + \vec{f}_i \vec{r}_i)$$

- Tensor product  $\vec{T} = \vec{u} \vec{v}$ , also denoted  $\vec{T} = \vec{u} \otimes \vec{v}$ ;  $T_{ab} = v_a v_b$ .
- $\phi = N/(N-1)$  takes into account 3 zero conserved momenta in periodic b.c.
- The scalar pressure is 1/3 of its trace,  $p = \text{tr}(\vec{P})/3$ .
- In models with rigid (constrained) bonds, the virial of constrained forces has to be included (it depends on velocities).
- Diagonal terms are good for calculating surface tension.
- Off-diagonal terms are good for calculating viscosity.\*
- Can be also calculated by the virtual box change:
  - elongation in  $\hat{x} \Rightarrow P_{xx}$ ,
  - simulation cell shape change  $\Rightarrow$  off-diagonal terms.

\*Surprisingly, the diagonal terms can be used to calculate viscosity, too.

### Pressure in the NVT ensemble: derivation 2/37 s07/4

$$dF = -SdT - pdV \quad (X) = \frac{1}{Q_N} \int_{V^N} X(r^N) d \exp[-\beta U(r^N)] r^N$$

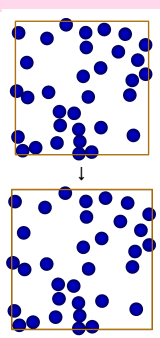

$$p = - \left( \frac{\partial F}{\partial V} \right)_T, \quad F = -k_B T \ln \frac{Q_N}{N! \Lambda^{3N}}$$

$$Q_N = \int_{V^N} \exp[-\beta U(r^N)] d r^N \quad r_i = V^{1/3} \xi_i \quad \int_{V^N} \exp[-\beta U(V^{1/3} \xi^N)] V^N d \xi^N$$

$$p = - \left( \frac{\partial F}{\partial V} \right)_T = k_B T \left( \frac{\partial \ln Q_N}{\partial V} \right)_{\xi^N} = \frac{k_B T}{Q_N} \left( \frac{\partial Q_N}{\partial V} \right)_{\xi^N}$$

$$= \frac{k_B T}{Q_N} \int_{V^N} \exp[-\beta U(V^{1/3} \xi^N)] N V^{N-1} d \xi^N$$

$$+ \frac{k_B T}{Q_N} \int_{V^N} \exp[-\beta U(V^{1/3} \xi^N)] (-\beta) \left( \frac{\partial U(V^{1/3} \xi^N)}{\partial V} \right)_{\xi^N} V^N d \xi^N$$

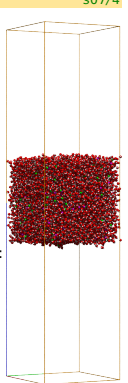

$$= \frac{N}{V} k_B T - \left\langle \left( \frac{\partial U(V^{1/3} \xi^N)}{\partial V} \right)_{\xi^N} \right\rangle = \text{ideal part (kinetic)} + \text{residual part (correction)}$$

### Surface tension of liquid + 7/37 s07/4

Using slab geometry – elongated periodic box (2:1 or more)

$$\gamma = \left( \frac{\partial V}{\partial A} \right)_{V,T} = \left( \frac{\partial G}{\partial A} \right)_{p,T} = -\frac{1}{4} L_z p_t, \quad \text{where } p_t = P_{xx} + P_{yy} - 2P_{zz}$$

- It is “mechanical quantity”.
- Cannot be used for interfacial energy of crystals (it is “entropic quantity”).
- Cutoff corrections – several variants (cf. simenon9).
- $P_{zz}$  = saturated vapor pressure; if small enough,  $P_{xx}, P_{yy}$  can be replaced by the usual pressure  $p$ .
- Alternative: virtual area change method [Gloor et al.: JCP 123, 134703 (2005)]: scaling in  $\hat{x}, \hat{y}$  and inversely squared in  $\hat{z}$  so that volume is preserved:
 
$$\gamma = \left\langle \left( \frac{\delta U}{\delta A} \right)_V \right\rangle$$

### Residual quantities 3/37 s07/4

= with respect to the standard state of ideal gas at the same temperature, volume (= density), and composition as the given system. Usefull in the canonical (NVT) ensemble.  
 sometimes called “excess”

For the Helmholtz energy:  $F = -k_B T \ln Z_N = -k_B T \ln \frac{Q_N}{N! \Lambda^{3N}} = -k_B T \ln \frac{V^N}{N! \Lambda^{3N}} - k_B T \ln \frac{Q_N}{V^N} \equiv F_{id} + F_{res}$  ideal gas:  $Q_N = V^N$

**Refresh:**  
 de Broglie thermal wavelength:  $\Lambda = \frac{h}{\sqrt{2\pi m k_B T}}$

chemical potential of ideal gas:  $\mu_{id} = \left( \frac{\partial F_{id}}{\partial N} \right)_{T,V} = k_B T \ln \frac{N \Lambda^3}{V}$

### Fluctuation quantities + 8/37 s07/4

$\langle (\Delta X)^2 \rangle = \text{Var } X =$  (mean quadratic) fluctuation = variance  
 fluctuation = (mech/el/... quantity)' = (thermodynamic potential)''  $\Delta X = X - \langle X \rangle$

**Less accurate than mean values!**  
 E.g. (NVT):  $P = - \left( \frac{\partial F}{\partial V} \right)_T, E = \left( \frac{\partial F}{\partial \beta} \right)_V$ , then:

- Heat capacity at constant [V]:  $C_V = \left( \frac{\partial E}{\partial T} \right)_V = \frac{1}{k_B T^2} \text{Var } E = \frac{1}{k_B T^2} \langle (\Delta E_{kin} + \Delta U)^2 \rangle$
- $\text{Cov}(U, E_{kin}) = \Delta U \Delta E_{kin} = 0, \text{Var } E_{kin} = \frac{1}{2} (k_B T)^2$  (see exercise)  $\Rightarrow$
- $C_V = \frac{1}{k_B T^2} \left\langle \left( \frac{f k_B T}{2} + \Delta U \right)^2 \right\rangle = \frac{f k_B}{2} + \frac{1}{k_B T^2} \langle (\Delta U)^2 \rangle \equiv C_{V,id} + C_{V,res}$
- Isothermal compressibility – in the NPT ensemble:  $\kappa = -\frac{1}{V} \left( \frac{\partial V}{\partial P} \right)_T = \frac{\langle (\Delta V)^2 \rangle}{V k_B T}$

Permittivity can be calculated from the fluctuation of the cell dipole moment,  $\langle M^2 \rangle$ , (more later).

### Pressure – virtual volume change method 4/37 s07/4

$$p = \frac{N}{V} k_B T - \left\langle \left( \frac{\partial U(V^{1/3} \xi^N)}{\partial V} \right)_{\xi^N} \right\rangle$$

**Numerical derivative** (for a selected series of configurations)

$$\frac{\partial U}{\partial V} = \frac{U(V + \Delta V) - U(V)}{\Delta V} + \mathcal{O}(\Delta V) \equiv \frac{U(\xi_i^N) - U(\xi_i^N)}{\Delta V} + \mathcal{O}(\Delta V)$$

$$\frac{\partial U}{\partial V} = \frac{U(V + \Delta V) - U(V - \Delta V)}{2\Delta V} + \mathcal{O}(\Delta V^2)$$

**Implementation:**  $U(V + \Delta V)$  means that the whole configuration (all distances) is swelled by the same ratio; for molecules w.r.t. a reference point (then,  $N = \#$  of molecules):

$$\left( \frac{V + \Delta V}{V} \right)^{1/3}$$

The scaled configuration is not included in the trajectory.

For models with a hard core such that swelling the box cannot cause an overlap, shrinking can be used:  $P = N k_B T / V + \frac{k_B T}{\Delta V} (e^{-[U(V-\Delta V) - U(V)]/k_B T} + \mathcal{O}(\Delta V))$

### Exercise + 9/37 s07/4

Calculate  $\langle E_{kin} \rangle$  and  $\text{Var}(E_{kin})$  for one degree of freedom,  $E_{kin} = \frac{1}{2} m v^2$ .

$$E_{kin} = \frac{1}{2} m v^2$$

$$\pi(v) = \frac{\exp(-\frac{1}{2} m v^2 / k_B T)}{\int \exp(-\frac{1}{2} m v^2 / k_B T) dv}$$

$$\langle E_{kin} \rangle = \int E_{kin} \pi(v) dv$$

$$\text{Var}(E_{kin}) = \int (E_{kin} - \langle E_{kin} \rangle)^2 \pi(v) dv = \frac{1}{2} (k_B T)^2$$

```

> restart;
> assume(m>0, k>0, T>0);
> k:=m/2*v^2: KT:=k*T:
> inorm:=int(exp(-K/KT),v=-infinity..infinity);
inorm:=sqrt(k-T)/sqrt(m-k-T);
> averk:=int((K*exp(-K/KT),v=-infinity..infinity)/inorm;
averk:=1/2*k-T;
> fluctk:=int((K-averk)^2*exp(-K/KT),v=-infinity..infinity)/inorm;
fluctk:=1/2*k-T^2;
  
```

### Pressure from the virial of force 5/37 s07/4

**The derivative expanded:**

$$\frac{\partial U(V^{1/3} \xi^N)}{\partial V} = \sum_{i=1}^N \frac{1}{3} V^{-2/3} \xi_i \cdot \frac{\partial U}{\partial r_i} = \frac{1}{3V} \sum_{i=1}^N \vec{r}_i \cdot \frac{\partial U}{\partial \vec{r}_i}$$

The result is

$$p = \frac{N}{V} k_B T + \frac{1}{3V} (W_f), \quad W_f = - \sum_{i=1}^N \vec{r}_i \cdot \frac{\partial U}{\partial \vec{r}_i} = \sum_{i=1}^N \vec{r}_i \cdot \vec{f}_i \quad (\text{virial of force})$$

... cannot be directly applied in the periodic boundary conditions.

- Pair additivity in the periodic boundary conditions  $\Rightarrow$
- $p = \frac{N}{V} k_B T - \frac{1}{3V} \sum_{\langle ij \rangle} (r_{ij} u'(r_{ij})) \equiv p_{id} + p_{res}$

- For molecular models one can use either the site-frame ( $N = \#$  of sites/atoms) or molecular frame ( $N = \#$  of molecules; typically, ref. point = center of mass). Of course, the formulas differ.

### Isochoric heat capacity $C_V$ in the NVE ensemble + 10/37 s07/4

In the **canonical** ensemble:

$$\text{Var } X = k_B T^2 \frac{\partial^2 X}{\partial T^2} \equiv k_B T^2 X' \quad (X = U, E_{kin}) \quad (1)$$

$$\text{Cov}(U, E_{kin}) = 0$$

$$C_V = U' + E'_{kin}, \quad E'_{kin} = \frac{f k_B}{2}$$

Unnormalized probability distribution for temperature  $T$ :

$$w(U, E_{kin}) \sim \exp \left[ -\frac{(\delta U)^2}{2 \text{Var } U} - \frac{(\delta E_{kin})^2}{2 \text{Var } E_{kin}} \right]$$

where the deviations are linearized:  $(U, E_{kin}) = (U_0 + \delta U, E_{kin,0} + \delta E_{kin})$

Unnormalized probability distribution taking into account change in temperature,  $T = T_0 + \delta T$ :

$$w(T, U, E_{kin}) \sim \exp \left[ -\frac{(\delta U - U' \delta T)^2}{2 \text{Var } U} - \frac{(\delta E_{kin} - E'_{kin} \delta T)^2}{2 \text{Var } E_{kin}} \right]$$

### Multiple histogram reweighting II

+ 21/37  
s07/4

In the simulation, we calculate the histogram  $h_i(E)$  for a set of (equidistant) energies  $E$ , or some equivalent Gaussian-based  $\delta$ -function approximation. We will use the normalized histogram and the  $\int$ -form. (To repeat, subscript  $i$  refers to  $T_i$ .)

$$\sum_E h_i(E) = \int h_i(E) dE = 1$$

$$h_i(E) = \frac{D(E)e^{-\beta_i E}}{\int D(E)e^{-\beta_i E} dE} = D(E)e^{-\beta_i(E-F_i)}$$

Using one temperature only but  $F_i$  is not known (yet):

$$D(E) = h_i(E)e^{\beta_i(E-F_i)} \quad (2)$$

- We will average  $D(E)$  from several simulations at different temperatures.
  - $D(E)$  does not depend on  $T_i$ , but our calculation does  $\pm$  statistical errors.
  - At different  $T_i$  different ranges of  $E$  are sampled.
- $\Rightarrow$  We compose the total  $D(E)$  from all data:

$$D(E) = \sum_i w_i(E) h_i(E) e^{\beta_i(E-F_i)}, \quad \sum_i w_i(E) = 1$$

### Multiple histogram reweighting III

+ 22/37  
s07/4

Determining the weights: minimization of the error  $\delta D(E)$  (or some estimate). Using reasonable assumptions, we get

$$w_i(E) = \frac{N_i h_i(E)}{\sum_j N_j h_j(E)} = \frac{N_i e^{-\beta_i(E-F_i)}}{\sum_j N_j e^{-\beta_j(E-F_j)}}$$

where  $N_i$  is the number of measurements at temperature  $\beta_i$ .  $\Rightarrow$

$$e^{-\beta_i F_i} = \int D(E) e^{-\beta_i E} dE = \int \sum_j w_j(E) h_j(E) e^{\beta_j(E-F_j)} e^{-\beta_i E} dE$$

$$= \int \frac{\sum_j N_j e^{-\beta_j(E-F_j)} h_j(E) e^{\beta_j(E-F_j)}}{\sum_j N_j e^{-\beta_j(E-F_j)}} e^{-\beta_i E} dE = \int \frac{\sum_j N_j h_j(E) e^{-\beta_j E}}{\sum_j N_j e^{-\beta_j(E-F_j)}} dE$$

can be solved by iterations (self-consistent solution).

$F_i$  are determined but an additive constant,  $D(E)$  but a multiplicative factor

### Multiple histogram reweighting IV

+ 23/37  
s07/4

Expectation value at temperature  $\beta$ :

$$\langle X \rangle_\beta = \frac{\int X(E) D(E) e^{-\beta E} dE}{\int D(E) e^{-\beta E} dE} = \frac{\int X(E) \frac{\sum_i h_i(E)}{\sum_j N_j e^{-\beta_j(E-F_j)}} e^{-\beta E} dE}{\int \frac{\sum_i h_i(E)}{\sum_j N_j e^{-\beta_j(E-F_j)}} e^{-\beta E} dE}$$

- $\int dE$  is over histograms of width  $\Delta E$
- if  $\Delta E$  is very short, all calculated energies are stored and  $\int X(E) h_i(E) dE$  is replaced by a sum of  $E$  over  $h_i(E) = 1/N_i$
- $\sqrt{\text{Var}E}/\langle E \rangle \approx N^{-1/2} \Rightarrow \beta_i/\beta_{i+1} \approx 1 \pm N^{-1/2}$  (overlapping distributions)

### Parallel tempering (replica exchange)

+ 24/37  
s07/4

$k$  simulations at temperatures  $\beta_1 < \beta_2 \dots$  are run in parallel.

Once a while, 2 subsystems  $\beta_i, \beta_j$  (normally  $|i-j| = 1$ ) are interchanged, the acceptance probability is

$$\min \left\{ 1, \frac{\exp(-\beta_j E_i - \beta_i E_j)}{\exp(-\beta_i E_i - \beta_j E_j)} \right\}$$

- Pros: easier barrier crossing, improved ergodicity, faster convergence at low temperatures
- Cons: correlations between subsystems, difficult error estimation

### Conformational flooding, metadynamics, Wang-Landau

25/37  
s07/4

Method suitable for fast **barrier crossing** (bad ergodicity - "bottleneck"), incl. calculation of the free energy profile ( $\Delta F$  or  $\Delta G$ ), based on decreasing the energy barrier.

- (several predecessors)
- Conformational flooding H. Grubmüller (1995)
- Wang-Landau (MC) F. Wang, D.P. Landau (2001)
- Metadynamics (MD) A. Laio, M. Parrinello (2002)
- Formal equivalence C. Junghans, D. Perez, T. Vogel (2014)

### Conformational flooding, metadynamics, Wang-Landau

26/37  
s07/4

- Our system is defined by the potential  $U_0(\vec{r}^N)$
- **Collective variable**  $\lambda = \lambda(\vec{r}^N)$  describes the studied process, e.g.: reaction coordinate, distance ligand-receptor (optionally + orientation), etc.  
There may be 2 or even more collective variables
- We simulate system with potential  $U(\vec{r}^N) = U_0(\vec{r}^N) + \Delta U(\lambda)$ , where  $\Delta U = 0$  at start
- $\Delta U(\lambda)$  is periodically updated:

$$\Delta U := \Delta U + \omega \frac{\delta(\lambda)}{h(\lambda)}, \quad \lambda = \lambda(\vec{r}^N)$$

- $\delta$  = approximation of  $\delta$ -function (MC: histogram bin, better and MD: Gauss)
- $\omega$  = small enough relaxation parameter,  $\omega \ll k_B T$
- $h(\lambda)$  = density of Cartesian points on hypersurface  $\lambda$ ; e.g.,  $h(\lambda) = 4\pi\lambda^2$  for  $\lambda = r_{12}$   
 $\Rightarrow$  the probability of visiting the same  $\lambda$  again decreases

### Conformational flooding, metadynamics, Wang-Landau

27/37  
s07/4

**Free energy profile** along  $\lambda$ :

- strictly, updating should be turned off in the final run (MC: microreversibility violation, MD: heating)
- then, the residual almost-uniform  $p(\lambda)$  is determined and:

$$F(\lambda) = \text{const} - \Delta U(\lambda) - k_B T \ln[p(\lambda)/h(\lambda)]$$

- in practice, with small enough  $\omega$  and continued updating, we can assume  $p(\lambda)/h(\lambda) = \text{const}$  so that (in the sampled region of  $\lambda$ )

$$F(\lambda) = \text{const} - \Delta U(\lambda)$$

**Free energy** of a well-define "basin" of states (e.g., a bond state) is:

$$F = -k_B T \ln \int_{\lambda_1}^{\lambda_2} e^{-F(\lambda)/k_B T} h(\lambda) d\lambda$$

integration over region for more collective variables

! symbols const are different

### Conformational flooding, metadynamics, Wang-Landau: Case study

[plot/metadynamics.sh 1 2] 28/37  
s07/4

3D system, interaction energy:

online simulation is for  $T=1$  K and  $T=2$  K, type [r] to reread

$$\frac{U_0(x, y, z)}{k_B K} = \phi(x)(y^2 + z^2 + 1), \quad \text{where } \phi(x) = [(x+1)(x+2)(x-2)(x-4) + 21] e^{(x+1.5)^2/3}$$

- The barrier is  $E^*/k_B = 1910$  K,  $e^{-E^*/k_B 1K} = 10^{-929}$
- Collective variable  $\lambda = x$
- Histogram: triangular  $\delta(\lambda)$ , grid = 1/100
- On purpose short MC step in  $x$  ( $\approx$  MD)
- Initial  $\omega = 0.25 k_B T$ , decrease to finish  
fine + stop ( $\omega \equiv a < 0$ ): aaaV in the plot window
- graphs shown:
  - running:  $\Delta U - F_{\text{exact}}$ , where  
 $F_{\text{exact}}(\lambda) = \phi(\lambda) + k_B T \ln(\phi(\lambda))$
  - final:  $\Delta U$  and  $\phi(x) = U_0(x, 0, 0)$
  - $F$  and  $F_{\text{exact}}$  comparison

Note: in real systems, the second term will be a result of many degrees of freedom, not just 2 ( $y, z$ )

### Parallel tempering (replica exchange)

+ 24/37  
s07/4

$k$  simulations at temperatures  $\beta_1 < \beta_2 \dots$  are run in parallel.

Once a while, 2 subsystems  $\beta_i, \beta_j$  (normally  $|i-j| = 1$ ) are interchanged, the acceptance probability is

$$\min \left\{ 1, \frac{\exp(-\beta_j E_i - \beta_i E_j)}{\exp(-\beta_i E_i - \beta_j E_j)} \right\}$$

- Pros: easier barrier crossing, improved ergodicity, faster convergence at low temperatures
- Cons: correlations between subsystems, difficult error estimation

### Conformational flooding, metadynamics, Wang-Landau: Case study

[xmaple -/maple/metadynamics-case-study.mwl] 29/37  
s07/4

The final graph shows  $F(x) + \Delta U(x)$  (two independent simulations  $T = 1$  K, different start)

1/grid	$\Delta F/k_B T$
50	37.85(8)
100	40.52(5)
200	40.98(5)
400	41.08(3)
exact*	41.13

where  $\Delta F$  is the difference between the right and left basins.

\* see Maple

### Widom particle insertion method I

30/37  
s07/4

Open system

$$dF = -SdT - pdV + \mu dN$$

$$\beta\mu = \left( \frac{\partial \beta F}{\partial N} \right)_{V,T} = - \left( \frac{\partial \ln Z_N}{\partial N} \right)_{V,T}$$

$$\beta\mu_{\text{res}} = \left( \frac{\partial \beta F_{\text{res}}}{\partial N} \right)_{V,T} = - \left( \frac{\partial \ln(Q_N/V^N)}{\partial N} \right)_{V,T} \approx - \left( \ln \frac{Q_{N+1}}{V^{N+1}} - \ln \frac{Q_N}{V^N} \right)$$

$$\exp(-\beta\mu_{\text{res}}) = \frac{1}{V} \frac{Q_{N+1}}{Q_N}$$

Or for the full chemical potential:

$$e^{-\beta\mu} = \frac{Z_{N+1}}{Z_N} = \frac{Q_{N+1}/[(N+1)! \Lambda^{3(N+1)}]}{Q_N/[N! \Lambda^{3N}]} = \frac{1}{(N+1)\Lambda^3} \frac{Q_{N+1}}{Q_N} \approx \frac{1}{N\Lambda^3} \frac{Q_{N+1}}{Q_N}$$

then by subtracting  $\mu^{\text{id}} = k_B T \ln \left( \frac{N\Lambda^3}{V} \right)$  we get the same  $\mu_{\text{res}} = \mu - \mu^{\text{id}}$

## Widom particle insertion method II

31/37  
s07/4

$$\exp(-\beta\mu_{res}) = \frac{1}{V} \frac{Q_{N+1}}{Q_N}$$

$$N \rightarrow N+1 \quad U_{N+1} = U_N + \Psi(N)$$

$$\frac{1}{V} \frac{Q_{N+1}}{Q_N} = \frac{1}{V Q_N} \int \exp(-\beta U_N - \beta \Psi) d\vec{r}_1 \dots d\vec{r}_{N+1} = \frac{1}{V} \int (e^{-\beta \Psi})_N d\vec{r}_{N+1}$$

$$\exp(-\beta\mu_{res}) = \frac{1}{V} \int (e^{-\beta \Psi})_N d\vec{r}_{N+1} = \langle (e^{-\beta \Psi})_N \rangle_{\text{random } \vec{r}_{N+1}}$$

where  $\frac{1}{V} \int X d\vec{r}_{N+1} = \langle X \rangle_{\text{random } \vec{r}_{N+1}}$  = mean value of  $X$  over positions of the  $(N+1)$ -th particle in volume  $V$ , calculated by MC integration (inserting a particle at random place)

- $(N+1)$ -th particle does not influence the system – it is virtual (fictitious, ghost)
- Problem: dense systems, large solutes

Remedy: gradual insertion (thermodynamic integration or by finite steps)

**Similar:** solute insertion  $\Rightarrow$  solubility, Henry constant

## Example

(cd .../maple: xmaple simul07+10+Widom.mw) 32/37  
s07/4

We have simulated  $N = 500$  Ar atoms (Lennard-Jones:  $\sigma = 3.405 \text{ \AA}$ ,  $\epsilon/k_B = 119.8 \text{ K}$ ) in a box of volume  $V = 15.791 \text{ nm}^3$  at temperature  $T = 150 \text{ K}$ . By the Widom method, we found that<sup>‡</sup>

$$\exp(-\mu_{res}/k_B T) = 0.749(3)$$

Calculate  $\mu^o$ , the chemical potential of Ar with respect to the standard state of ideal gas at pressure  $p^{\text{st}} = 1 \text{ bar}$  and temperature  $T$ .

**Hints:**

$$\mu_{res} = \mu - \mu^{\text{id}}(T, V) \quad (N \text{ particles in volume } V)$$

$$\mu^o = \mu - \mu^{\text{id}}(T, V^{\text{id}}) \quad (V^{\text{id}} = \text{volume of ideal gas of } N \text{ particles at } T, p^{\text{st}})$$

$$\mu^o = \mu_{res} + \mu^{\text{id}}(T, V) - \mu^{\text{id}}(T, V^{\text{id}})$$

$$= \mu_{res} + k_B T \ln \frac{N k_B T}{p^{\text{st}} V}$$

$$\mu^{\text{id}}(V) = k_B T \ln \frac{N \Lambda^3}{V}$$

<sup>‡</sup>The value in parentheses is the estimated standard uncertainty in the unit of the least significant digit.

## Henry constant

+ 33/37  
s07/4

Gas (2) dissolved in liquid (1), mole fraction in liquid  $x_2 = N_2/(N_1 + N_2)$ ,  $x_2 \ll 1$ . One form of the Henry law for partial pressure  $p_2$  of (2) in equilibrium with solution:

$$p_2 = K_H x_2$$

By virtual insertion of one molecule ( $N_2 = 1$ ) of gas (2) to pure liquid (1), we get the residual chemical potential of (2) at  $x_2 = 1/(N_1 + 1) \approx 1/N_1$ ,

$$\mu_{res,2} = \mu_2(x_2) - \mu_2^{\text{id}}(V)$$

In equilibrium:

$$\mu_2(x_2) \stackrel{\text{eq!}}{=} \mu^{\text{id}}(V_2) = k_B T \ln \frac{\Lambda^3}{V_2}$$

$$\left. \begin{aligned} \mu_{res,2} &= k_B T \ln \frac{N_2 \Lambda^3}{V_2} - k_B T \ln \frac{N_2 \Lambda^3}{V} = k_B T \ln \frac{V}{V_2} \\ \mu^{\text{id}}(V) &= k_B T \ln \frac{N \Lambda^3}{V} \end{aligned} \right\}$$

where  $V_2$  is the volume corresponding to pressure  $p_2$  (don't forget that  $N_2 = 1$ ),

$$V_2 = \frac{1 k_B T}{p_2} = \frac{k_B T}{x_2 K_H} = \frac{k_B T N_1}{K_H}$$

where  $\rho_1 = N_1/V$  = number density of liquid (1). Finally,

$$K_H = \frac{\rho_1 k_B T}{e^{-\beta \mu_{res,2}}} = \frac{\rho_1 k_B T}{\langle (e^{-\beta \Psi})_{N_1} \rangle_{\text{random insertion of (2)}}}$$

## Reversible work by integrating the mean force

34/37  
s07/4

From thermodynamics:

$$\Delta G = W_{\text{other than pressure-volume}} [\rho, T]$$

$$\Delta \mu_i = - \int_{\vec{r}_i(1)}^{\vec{r}_i(2)} \langle \vec{f}_i \rangle \cdot d\vec{r}_i$$

where  $\vec{f}_i = -\partial U / \partial \vec{r}_i$  is the force acting on particle  $i$   
Molecules: the force applies to the center of mass or other reference point.

## Mean force and its potential

+ 35/37  
s07/4

Let us define the **single-particle density** as (also denoted as  $n_1$ )

$$\rho_1(\vec{r}_1) = \frac{N}{Q_N} \int e^{-\beta U(\vec{r}_1, \dots, \vec{r}_N)} d\vec{r}_2 \dots d\vec{r}_N$$

–  $\rho_1(\vec{r}_1) d\vec{r}_1$  is the probability of finding a particle (any one) in  $d\vec{r}_1$   
– extension to mixtures:  $N/Q_N \rightarrow N_{\text{species}}/Q_N$

The **potential of mean force** is defined by

$$\bar{U}_1(\vec{r}_1) = -k_B T \ln[V \rho_1(\vec{r}_1)]$$

The corresponding force is

$$\vec{f}_i = - \left( \frac{\partial \bar{U}_1}{\partial \vec{r}_1} \right) = k_B T \frac{\partial \rho_1 / \partial \vec{r}_1}{\rho_1} = \left\langle - \left( \frac{\partial U}{\partial \vec{r}_1} \right) \right\rangle_{\vec{r}_2, \dots, \vec{r}_N} = \langle \vec{f}_i \rangle_{\vec{r}_2, \dots, \vec{r}_N}$$

i.e., it is indeed the mean force on particle 1 held at fixed position  $\vec{r}_1$ .

Note: Similarly, for a 2-particle distribution, which for a pair of particles in an isotropic fluid is  $g(r)$ , one defines the potential of mean force as:

$$\bar{U}_2(r) = -k_B T \ln[g(r)]$$

## Interfacial (surface) energy of solids

+ 36/37  
s07/4

**Cleaving** [Davidchack, Laird: JCP 118, 7651 (2003)]: Thermodynamic integration over a gradually growing “knife” (e.g., Gaussian potential) inserted between crystallographic planes.

**Molding** [Espinosa, Vega, Sanz: JCP 141, 134709 (2014)]: Thermodynamic integration over a gradually growing “mold” (potential wells) to keep a crystal growing in a part of the system.

● General problem of both methods: hysteresis

## Gibbs energy of crystals

+

● Einstein crystal<sup>§</sup> at given  $T$  as a reference, integration over a coupling parameter [Frenkel, Ladd: JCP 81 3188 (1984), Frenkel, Mulder: Mol. Phys. 55, 1171 (1985)].

● Classical method: harmonic vibrations as a reference, thermodynamic integration of the difference  $0 \rightarrow T$  [Kolafa JCTC 15, 68 (2019) and references therein]

<sup>§</sup>independent harmonic oscillators, here treated classically

## Local density/concentration method

+ 37/37  
s07/4

Let a solute  $i$  be a subject of external potential  $U_i^{\text{ext}}(\vec{r})$  (e.g., “gravity”). In equilibrium:

$$\mu_i(\vec{r}) + U_i^{\text{ext}}(\vec{r}) = \text{const}$$

or

$$\mu_i(\vec{r}_1) - \mu_i(\vec{r}_2) = -[U_i^{\text{ext}}(\vec{r}_1) - U_i^{\text{ext}}(\vec{r}_2)]$$

We determine the concentration or density at  $\vec{r}_1$  and know the chemical potential (with respect to a certain reference)

**Example:**

- reference = infinite dilution approximation ( $\gamma = 1$ ) in the region of small concentration
- the activity coefficient  $\gamma$  in the region of high concentration can be calculated
