# Trends in sample preparation: innovative strategies from trace elements to metalloproteins

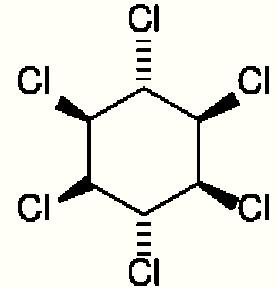

Marco Aurélio Zezzi Arruda

Associate Professor

GEPAM - <http://gepam.iqm.unicamp.br>

e-mail: [zezzi@iqm.unicamp.br](mailto:zezzi@iqm.unicamp.br)

# Sample preparation: why?

Lindane determination in vegetable samples

1,2,3,4,5,6-hexamethylcyclohexane

Water: 90 – 96%

Fibers: 0.4 – 1.8%

Starch: 0 – 0.6%

Salts: 0.4 – 0.7%

Fat: 0 – 1.3%

Proteins: 0.7 – 1.2%

Homogenization

Can the sample be  
directly injected ???

**NON VOLATILE MATERIALS  
PRESENT IN SAMPLE MATRIX**

Incompatible with GC!!!

(columns/injectors occlusion)  
(contaminant introduction)  
(artifacts formation)

# SURFACTANT

(*Surface active agent*)

**R-X structure**

**R: hydrocarbon chain (8-18 atoms)**

**X: polar or ionic head group**

**hydrophilic + hydrophobic groups → dissolution in water or other solvents**

# SURFACTANT

- **Non-ionic**

**Brij 35**, Polyoxyethylene(23);  $\text{CH}_3(\text{CH}_2)_{11}(\text{OCH}_2\text{CH}_2)_{23}\text{OH}$

- **Anionic**

**SDS**, Sodium dodecyl sulfate;  $\text{CH}_3(\text{CH}_2)_{11}\text{OSO}_3^-\text{Na}^+$

- **Cationic**

**CTAB**, Cetyl trimethyl ammonium bromide;  $\text{CH}_3(\text{CH}_2)_{15}\text{N}^+(\text{CH}_3)_3\text{Br}^-$

- **Amphoteric (Zwitterionic)**

**DAB**, 4-(Dodecyldimethyl ammonium) butirate

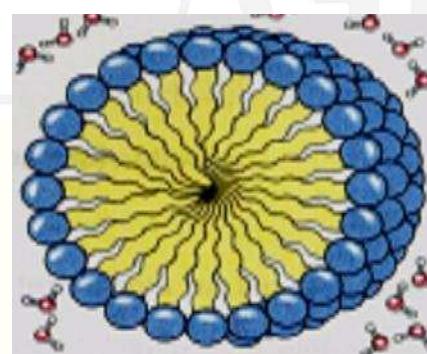

# The aggregate micellar formation

Amphiphilic molecules → self association in several solvents

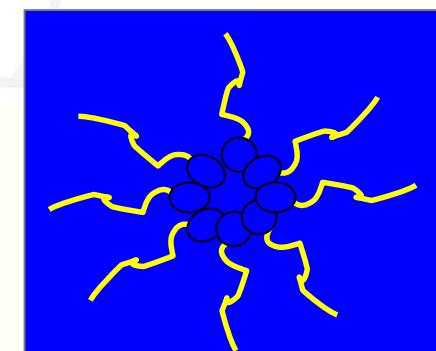

organized medium  
(microscopically ordered  
molecular aggregates)

normal micelle

bi-layers  
vesicles  
micro emulsions

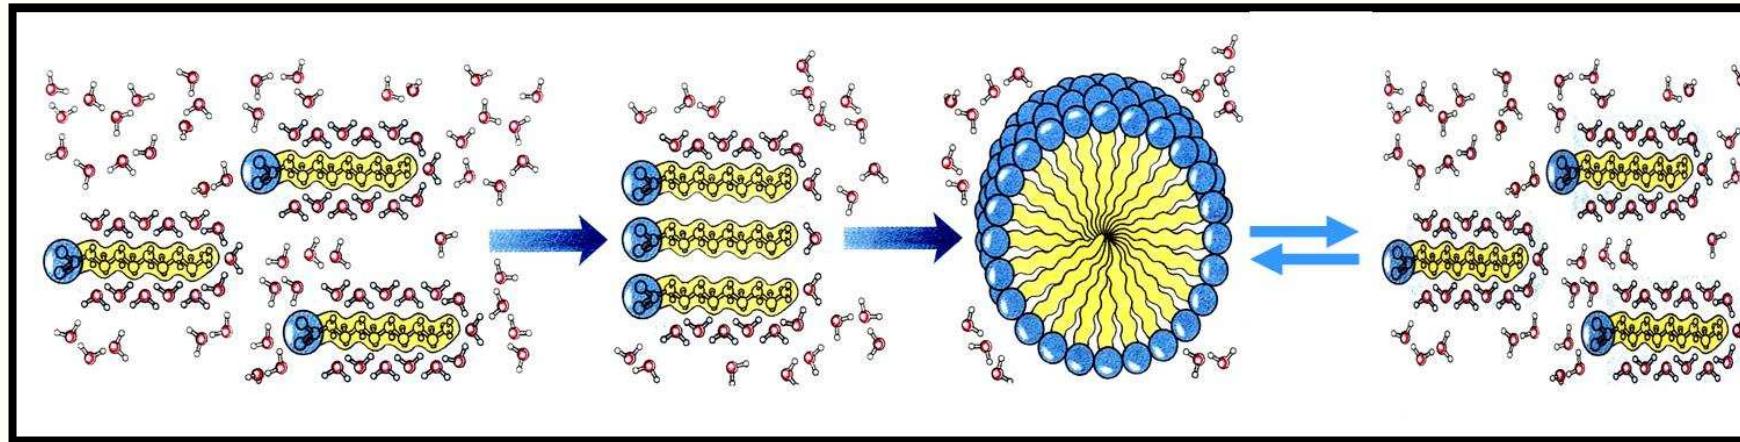

reversed micelle

final structure: monomer, solvent, surrounding ions

# The aggregate micellar formation

**monomers  
(below the CMC)**

**micelles and monomers in  
dynamic equilibrium  
(above the CMC)**

# Micellar medium in analytical chemistry

- water solubilization of hydrophobic substances
  - enhancing detection (spectrophotometric methods)
  - improvement on transport and nebulization (AAS methods)
  - catalytic reactions
  - extraction
  - preconcentration
- }
- CPE**

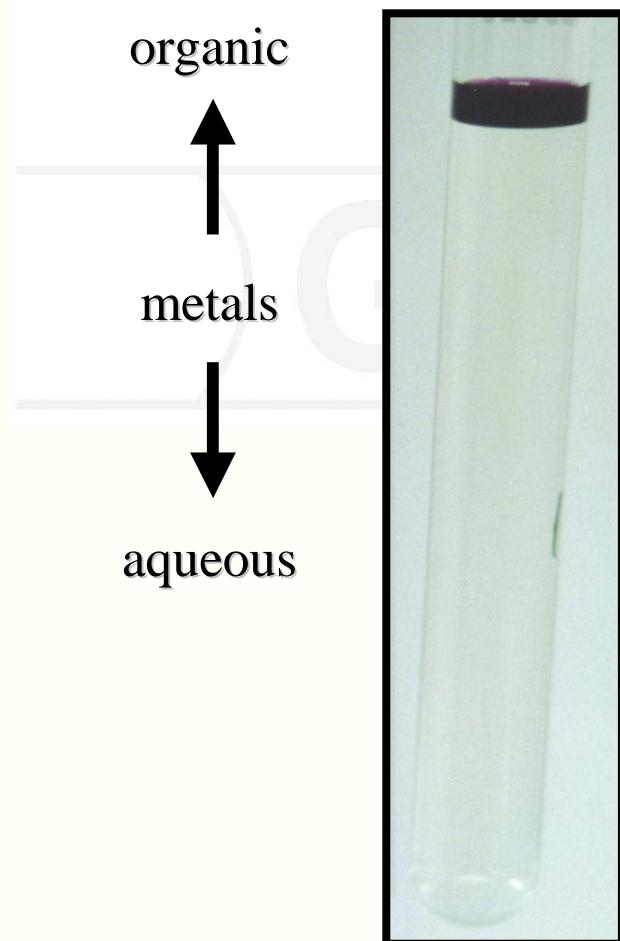

# Cloud point extraction – CPE

## Extraction mechanism

Bezerra et al., *App. Spectrosc. Review* 40(2005)269

surfactant molecules act as organic solvent

CPE efficiency:

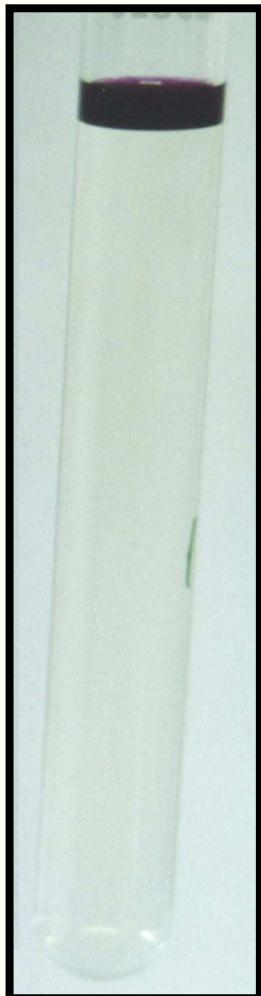

- 1) formation constant of the metallic complexes;
- 2) kinetics of complexation reaction;
- 3) phase transference of metallic species or chelate into micelle medium

# Cloud point extraction – CPE

## Extraction mechanism

Bezerra et al., *App. Spectrosc. Review* 40(2005)269

- - hydrated nature of the surfactant phase → distribution coefficient (D) lower than conventional LLE
- LLE: > ionic strength does not seriously modify extraction efficiency; CPE: salt addition → increase on phase separation

# Cloud point extraction – CPE

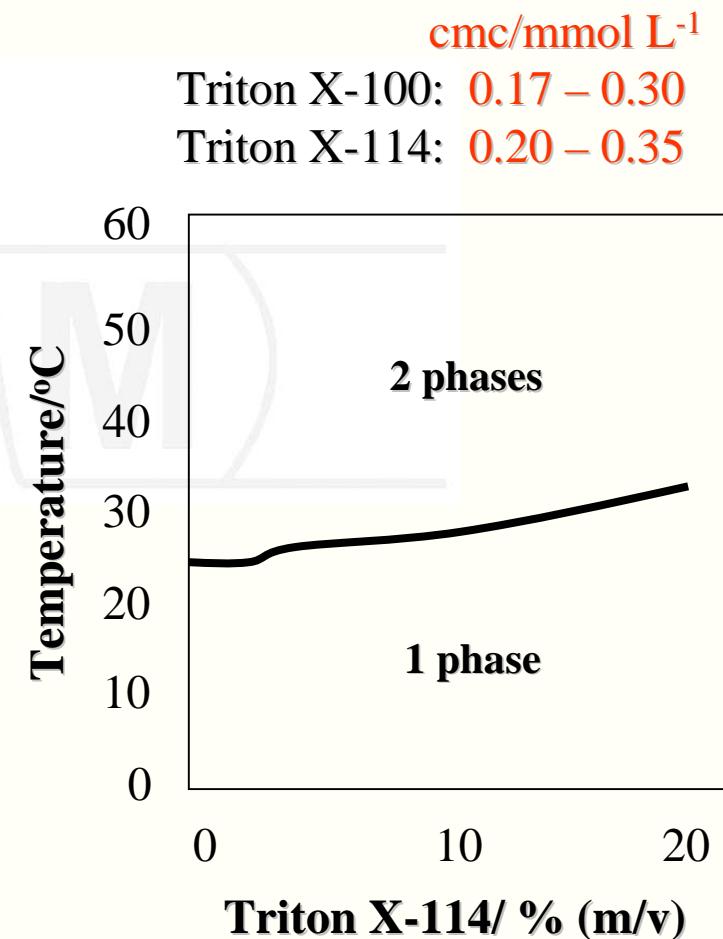

## Extraction mechanism

Gu & Sjöblom, *Colloids Surf.* 64(1992)39

Surfactant	T/°C
C <sub>6</sub> E <sub>3</sub>	40.5

# Ultrasound – US Conclusions

Simple and robust

Multi-elemental (?)

Low costs

Reduced residual acidity

Low sample throughput

Metrological trustable (?)

Extraction success → interactions between analyte-sample

Marco A. Z. Arruda

# Microwave assisted water extraction-MAWE

- ✓ Advantages:

- ✓ No cost and abundant substance
- ✓ Changes in its polarity by changing T
- ✓ Clean extraction methods

- ✓ Limitations:

- ✓ Low significance as extracting agent when not assisted by auxiliary energies

- ✓ Alternative extraction when assisted by:

- ✓ High temperature – high pressure
- ✓ Microwave radiation
- ✓ Ultrasound

# Microwave assisted water extraction-MAWE

## water $\longleftrightarrow$ microwaves interaction

- ✓ High dielectric constant compound necessary for producing heating when MW is used (presence of water!!)
- ✓  $\ggg T \rightarrow <$  viscosity. MW penetrates into sample destroying macrostructure of the matrix
- ✓ T and P produce a decrease on polarity with increases on analytes solubility. Process completely different to conventional extraction  $\rightarrow$  solvent diffusion through the sample and analytes are removed from matrix by solubilization

# Microwave assisted water extraction-MAWE

## water properties

- ✓ Polarity modified by temperature
- ✓ P and room temperature:
  - ✓ Dielectric constant (80) – extremely polar solvent, favoring the solubility of high polarity compounds
- ✓ High T and high P (water in liquid phase)
  - ✓ Lower dielectric constant, favoring the solubility of compounds presenting low polarity
    - ✓ Example: water (at 250°C)/ $\epsilon = 27$
    - ✓ ethanol/ $\epsilon=24$ ; methanol/ $\epsilon=33$  (at room T)
  - ✓ Water at high T contributes to the non-polar compounds solubility increases: benzo(e)pyrene solubility increases 25 million times (water → from room T to 350°C)
  - ✓ Extraction varying from ionic analytes to non-polar compounds

# Microwave assisted water extraction-MAWE

## Focused Microwave Assistance for Extracting Some Pesticide Residues from Strawberries into Water before Their Determination by SPME/HPLC/DAD

Clara Falqui-Cao, Zhi Wang, Louise Urruty, Jean-Jacques Pommier,<sup>†</sup> and Michel Montury\*

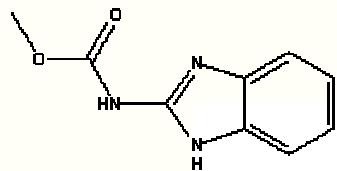

Equipe Périgourdine de Chimie Appliquée, Laboratoire de Physico et Toxicobiologie des Systèmes Naturels  
UMR 5472, Université Bordeaux 1/CNRS, BP 1043, 24001 Périgueux Cedex, France and Centre  
Interrégional de Recherche et d'Expérimentation de la Fraise, 24130 Prigonrieux, France

A novel and simple method for the determination of some pesticide residues in strawberries using both focused microwave-assisted extraction (FMAE) and solid-phase micro extraction (SPME), coupled with high-performance liquid chromatography (HPLC), has been developed. The pesticides were first extracted from strawberries with water and the assistance of focused microwaves at 30 W for 7 min. Then, an aliquot of the resulting aqueous extract was subjected to SPME with a 60- $\mu$ m thick poly(dimethylsiloxane)/divinylbenzene (PDMS/DVB) fiber for 45 min at room temperature, with the solution being stirred at 1000 rpm. The extracted pesticides on the SPME fiber were desorbed into the SPME/HPLC interface for quantitative analysis with a diode array detector (DAD). The whole sample pretreatment procedure before chromatographic analysis did not use any organic solvents or involve any blending or centrifugation steps. The five compounds (carbendazim, diethofencarb, azoxystrobin, napropamide, and bupirimate) were chosen because they cannot be analyzed easily by GC. The efficiency of this relatively fast procedure was comparable to that of previously reported methods, with detection limits at low  $\mu$ g/kg levels and linear responses in the range from 0.05 to 1 mg/kg of pesticide in strawberries, with RSDs between 3 and 7.3%, depending on the analyte. In all but one case results obtained by this method for field-incurred samples were comparable to those obtained with traditional methods.

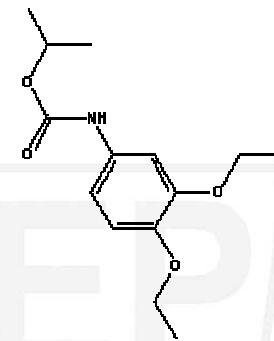

Marco A. Z. Arruda

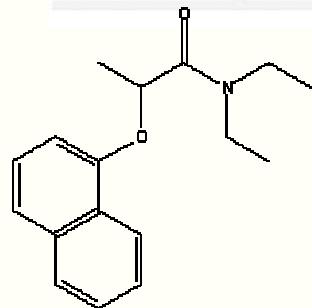

# Microwave assisted water extraction-MAWE

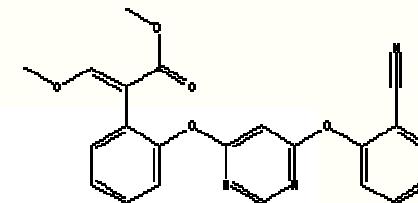

Carbendazim  
[C<sub>9</sub>H<sub>9</sub>N<sub>3</sub>O<sub>2</sub>]

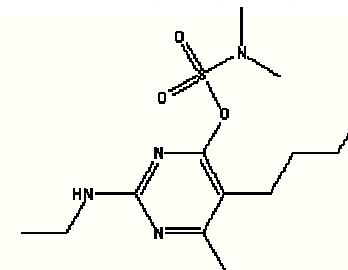

Diethofencarb  
[C<sub>14</sub>H<sub>21</sub>NO<sub>4</sub>]

Napropamide  
[C<sub>17</sub>H<sub>21</sub>NO<sub>2</sub>]

Bupirimate  
[C<sub>13</sub>H<sub>24</sub>N<sub>4</sub>O<sub>3</sub>S]

# Microwave assisted water extraction-MAWE

- ✓ Extraction:

- ✓ FMAE
- ✓ SPME – direct analytes transference to the PDMS/DVB fiber  
*via* pure water

Matrix processing and centrifugation are avoided

- ✓ Quantification: HPLC

# Microwave assisted water extraction-MAWE

- ✓ Samples:

- ✓ synthetic (contamination by adding the analytes)
- ✓ real

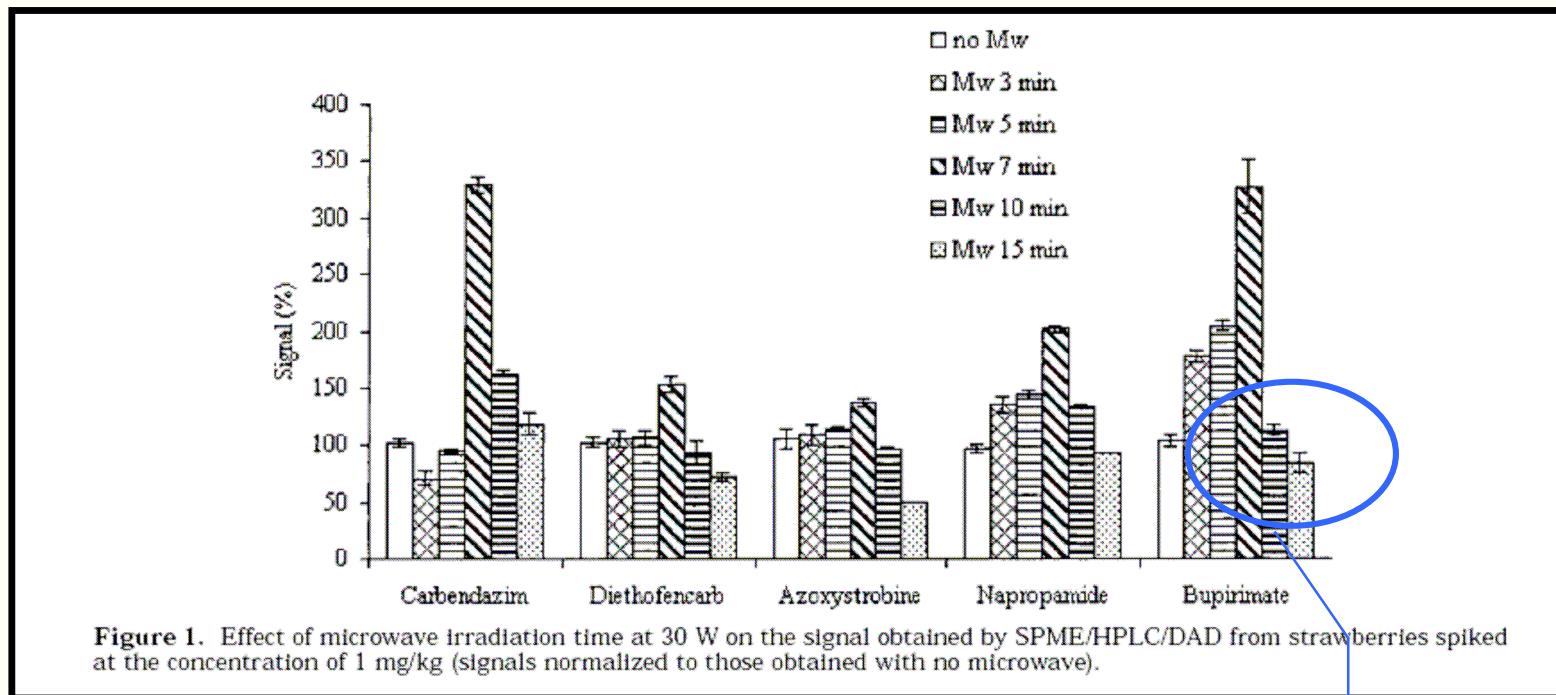

- ✓ Optimization:

- ✓ SPME – through literature and manufacturer information
- ✓ FMAE – time of fiber exposition (at a fixed power)

# Microwave assisted water extraction-MAWE

## Extraction efficiency

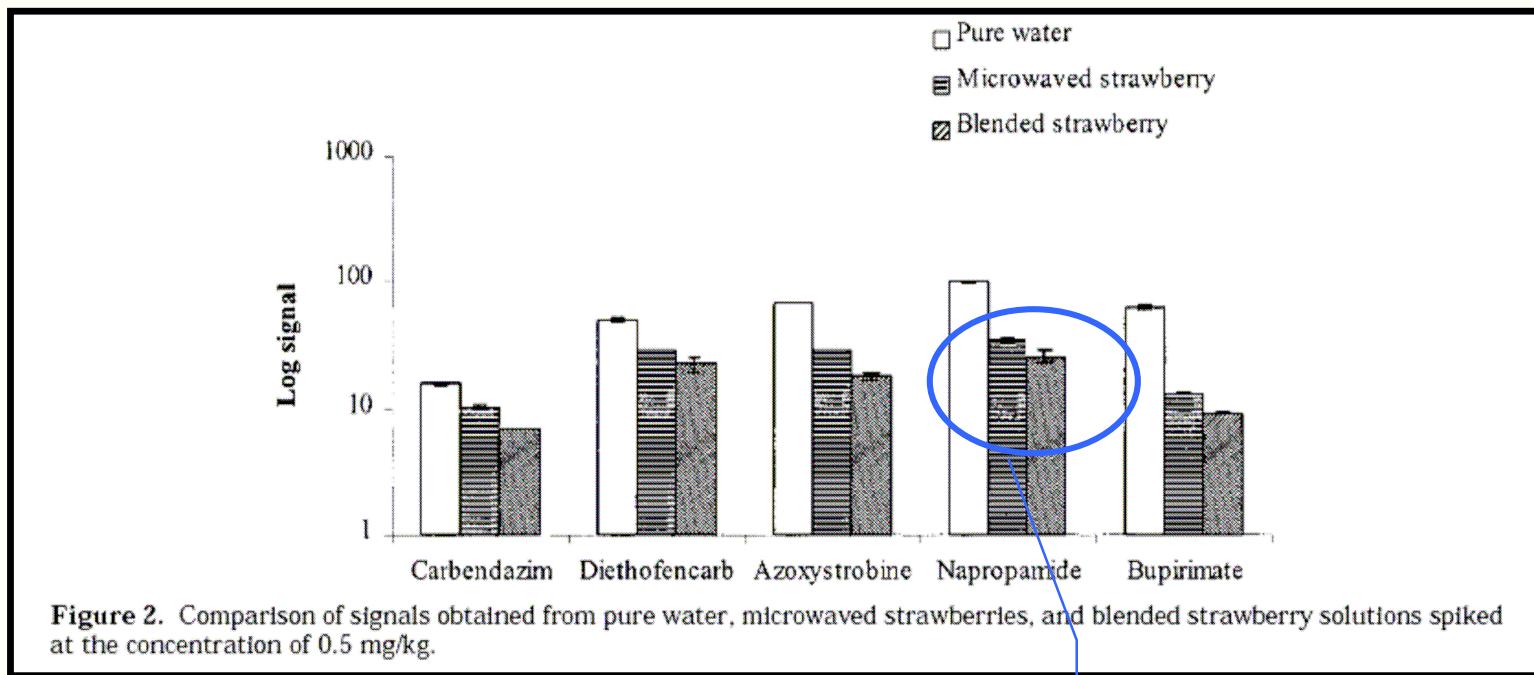

↑ Power  
↑ T  
→ analytes degradation

# Microwave assisted water extraction-MAWE

## Recoveries

**Figure 2.** Comparison of signals obtained from pure water, microwaved strawberries, and blended strawberry solutions spiked at the concentration of 0.5 mg/kg.

Matrix effect:

- lower recoveries

Extraction efficiency:

- FMAE ↑

# Microwave assisted water extraction-MAWE

#### Abstract

The growing trend both to avoid the use of organic solvents and reduce the time needed to extract pollutants from environmental solid samples has led to the use of water assisted by auxiliary energies for leaching. The most common of the auxiliary energies used are high pressure–high temperature, microwaves and ultrasounds. One of the most interesting aspects of the use of water in combination with auxiliary energies is the possibility of coupling extraction with other steps of the analytical process, thus enabling partial or total automation of the analytical process, so it is expedited. The addition of reagents (such as surfactants, acids, etc.) to water enlarges its field of application and provides an additional way of shortening the leaching time; thus allowing the establishment of environmental friendly methods. A review about the potential of water as extractant and its main applications so far is here presented.

# Biomimetic Receptors

## *Molecularly Imprinted Polymers (MIP)*

Synthetic polymers presenting selectivity to a target molecule

Science tries to imitate those natural recognition sites

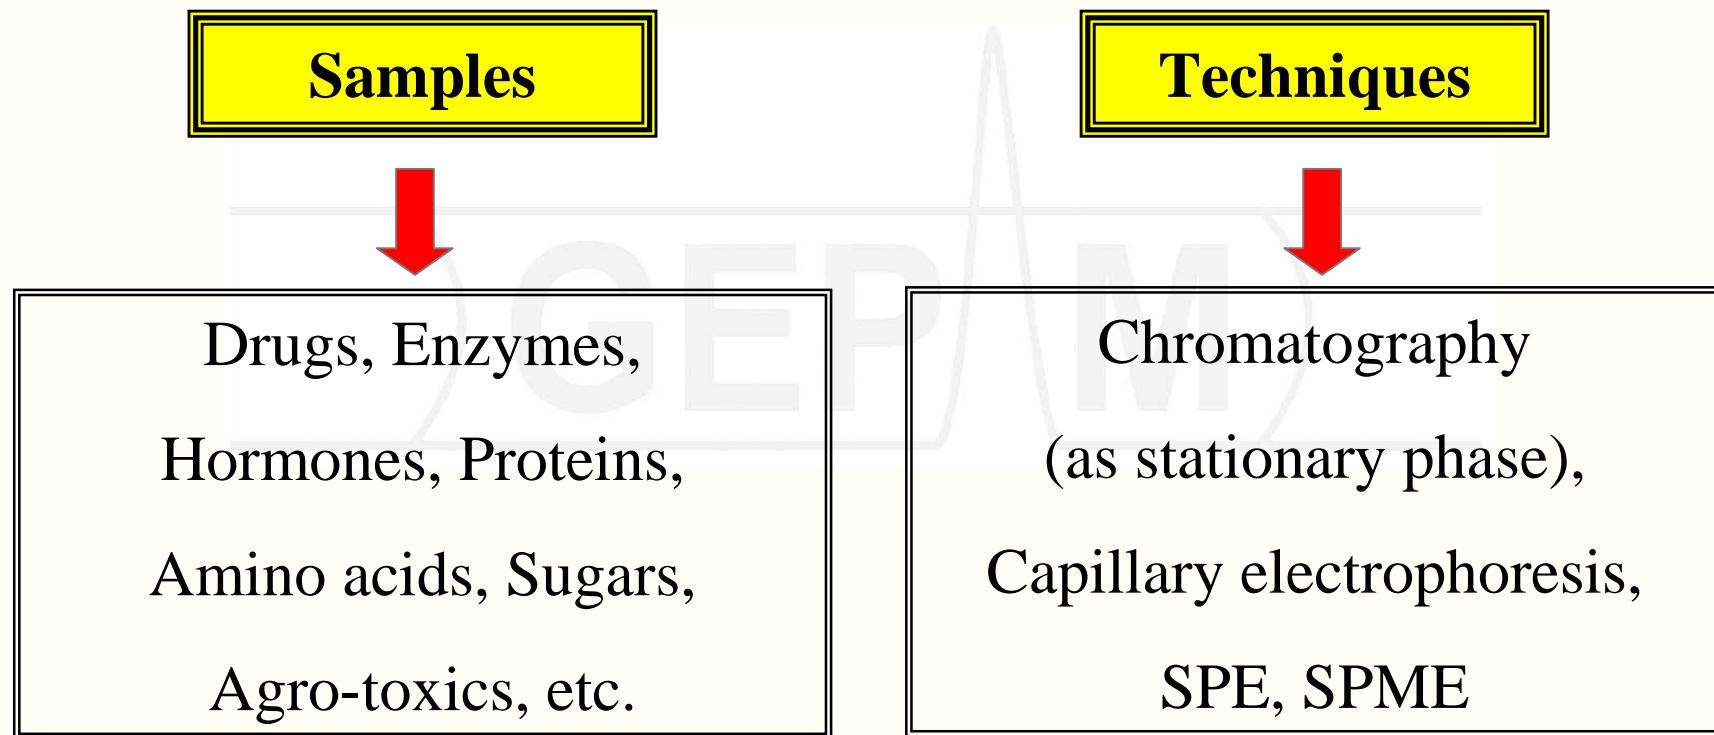

Antigen/**Antibody**

Enzyme/**Substrate**

Drug/**Receptor**

# MIPs: Application to the Analytical Chemistry

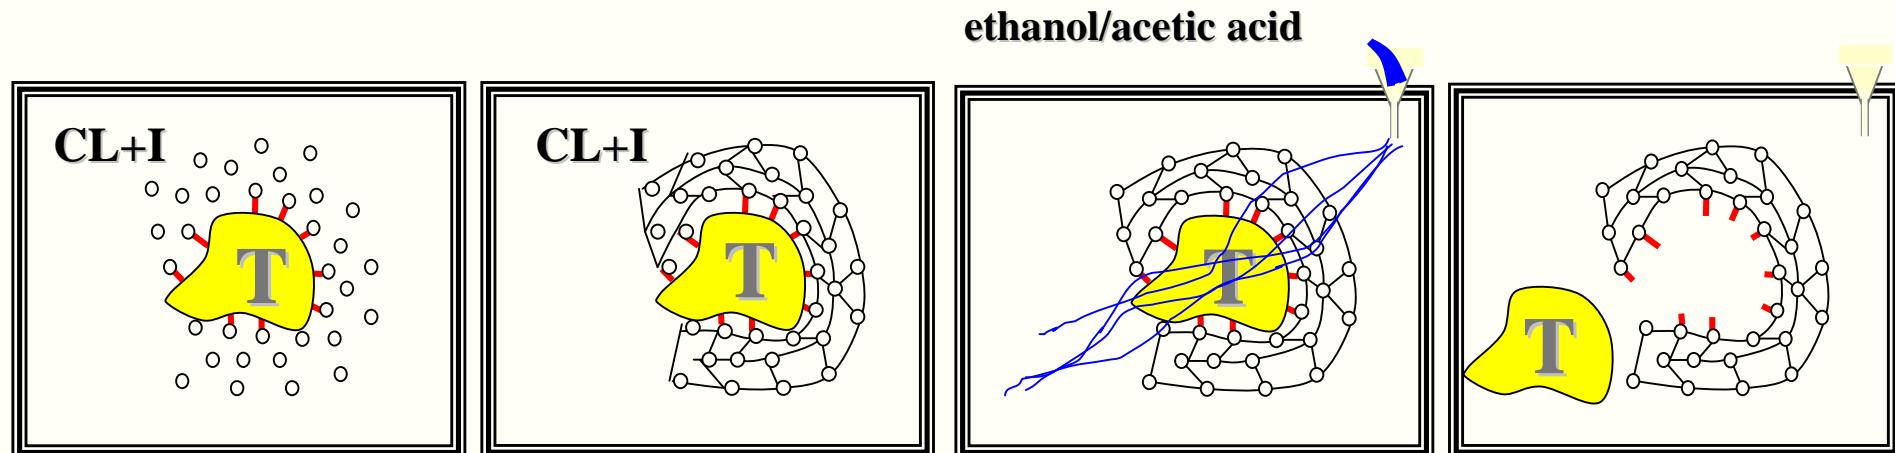

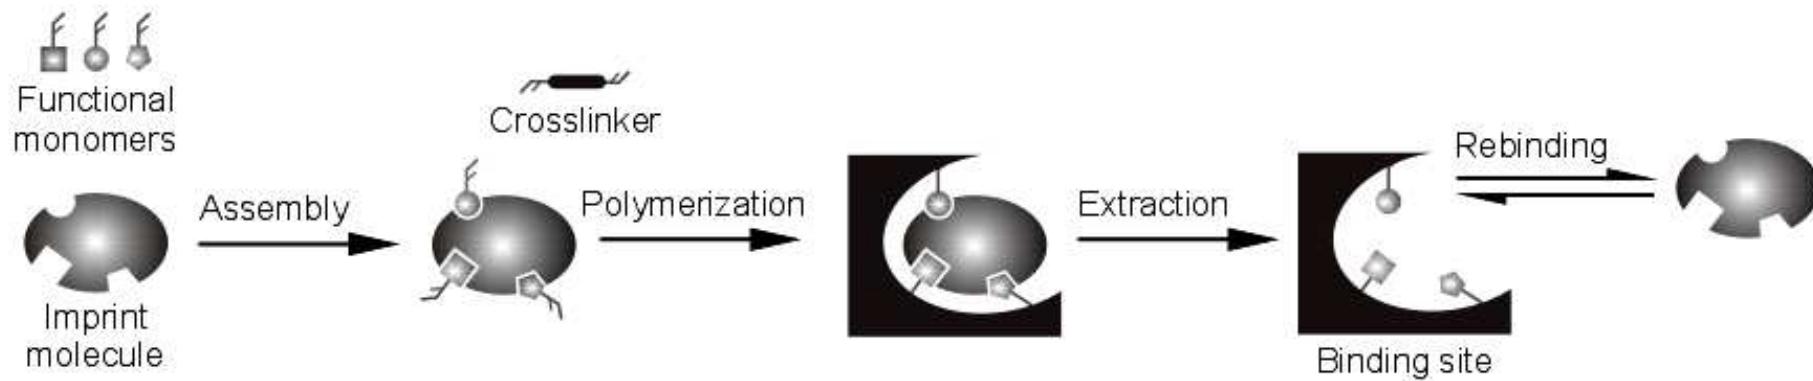

# MIP – Synthesis

Marco A. Z. Arruda

Medium (solvent, water); Template (IM); Functional monomer (FM); Cross-linker (CL); Initiator (I)

# MIP – Reagents

## Imprinted molecule – IM

- has specific groups to promote the bond to the FM
- no presence of polymerizable groups (insertion to the polymeric net)
- no groups that increase or decrease the polymerization reaction  
(ex. tyol groups)
- stability (T ca. 60°C)

# MIP – Reagents

## Functional monomer – FM

- Complementarities between FM and IM.
- if FM is proton donor (acidic character) → IM must be proton acceptor (basic character) and *vice-versa*
- Commonly used: methacrylic acid (for basic IM) and 4-vinylpyridine (for acidic IM)
- Concentration: interaction between FM and IM is based on equilibrium processes. >> [FM] than [IM] - ca. 4:1 [FM]:[IM] → formation of a great number of specific recognizing sites
- Possibility of combining different FM → polymerization cocktail

# MIP – Reagents

acrylic acid

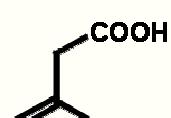

methacrylic acid

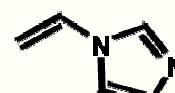

trifluoro-methacrylic acid

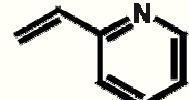

4-vinylbenzoic acid

itaconic acid

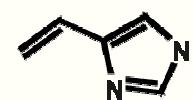

1-vinylimidazole

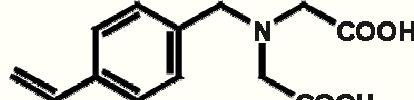

2-vinylpyridine

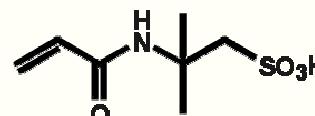

4-vinylpyridine

4(5)-vinylimidazole

4-vinylbenzyl-iminodiacetic acid

2-acrylamido-2-methyl-  
1-propane sulphonic acid

FM

Marco A. Z. Arruda

# MIP – Reagents

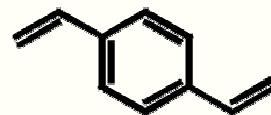

## Cross-linker – CL

-Function:

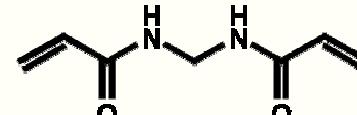

- \*morphology control of the polymeric matrix
- \*stabilizes the bond sites
- \*promote mechanical stability to the polymer
- necessary at higher proportions in the MIP synthesis → to access the porous of the polymer, guarantying mechanical stability
- Ethylene glycol dimethacrylate → commonly used

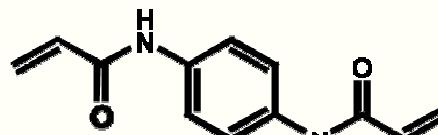

# MIP – Reagents

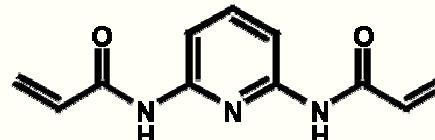

4-divinylbenzene

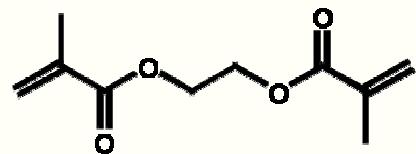

N,N'-methylene-bisacrylamide

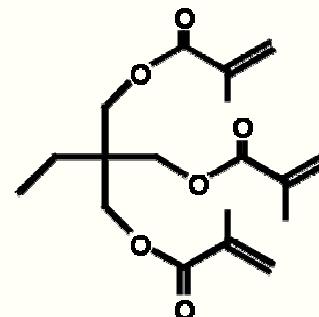

N,N'-phenylene-bisacrylamide

2,6-bisacrylamidopyridine

ethylene glycol dimethacrylate

trimethylolpropane  
trimethacrylate

Cross-linker

# MIP – Reagents

## Solvent

-Function:

- \* reagents solubilization in the synthesis
- \*contribute to best porous formation
- \*contribute to macro-porous formation in the polymer → large surface area
- does not interfere in the complex FM-IM formation (probability to form low selective sites and in less quantities)
- majority of the interactions between FM-IM is due to the electrostatic forces and hydrogen bounds → solvents should present non polar characteristics and have lower dielectric constant (e.g. chloroform and toluene)
- solubility problems: uses acetonitrile. MIP presenting lower selectivity can be formed

# MIP – Reagents

## Initiator - I

- Function: creates free radicals for polymerization
- external stimulus: T, UV radiation
- check its influence on others reagents (T increase without its degradation?, etc.)
- commonly used: 2,2'- azobisisobutyronitrile

### Caution:

- synthesis processed at 60°C as maximum T (azobisisobutyronitrile)
- it must be carried out in an oxygen-free atmosphere

# MIP – Synthesis: Reagents

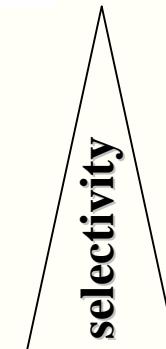

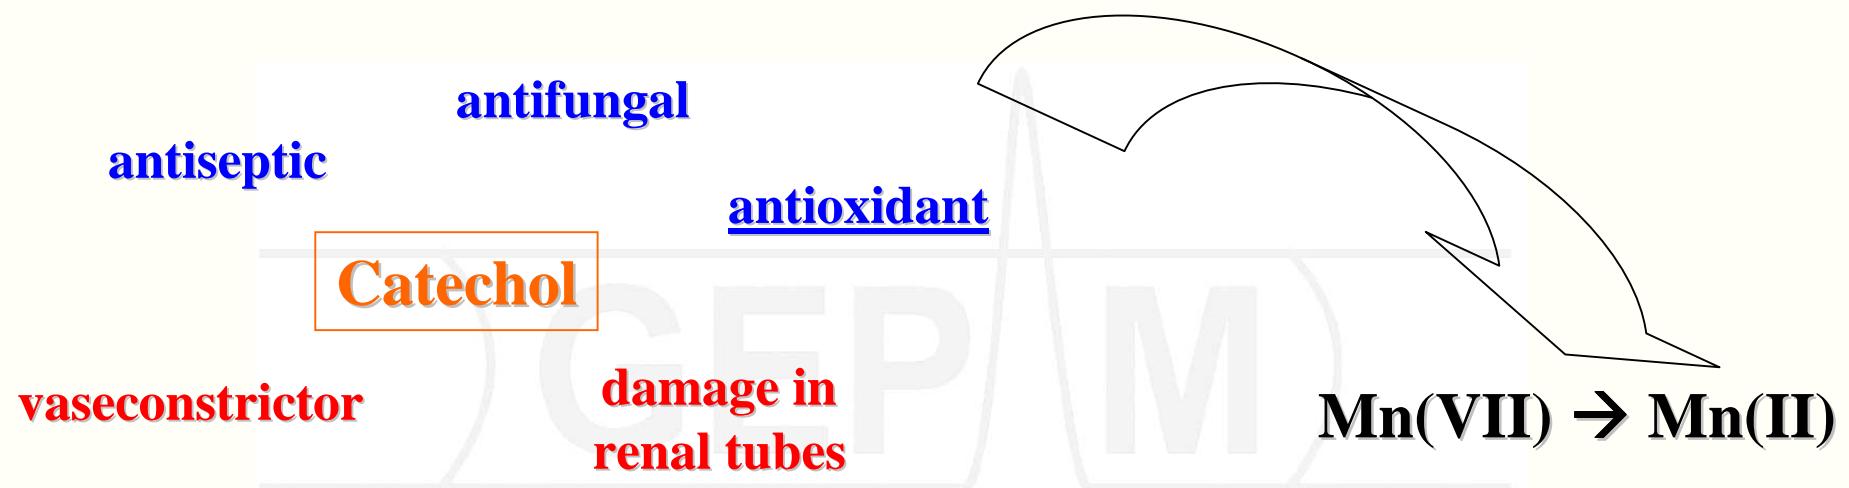

Medium	Chloroform/acetonitrile
Functional monomer	Methacrylic acid (MA) used for basic molecules 4 vinylpyridine (4VP) used for acidic molecules
Cross-linker	Ethylene glycol dimethacrylate (EGDA).
Initiator	Azobisisobutyronitrile

# MIP – Applications

# Some definitions

**METALLOME:** Set of metals or metalloids inside a cell or tissue – *ionome* and *metalloproteome*

*Ionome:* Metal (free) contained in a cell

*Metalloproteome:* Set of complexed metals with proteins in a cell

**METALLOMICS:** Study (quali and quantitative) of the metallome

HARAGUCHI, 2002

# Examples of metalloenzymes (and metalloproteins)

Element	Enzymes/Proteins
Selenium	<i>Glutathione peroxidase</i> . An enzyme that catalyzes the reduction of peroxides and protects the cells from oxidative damage
Chromium	<i>Transferrin</i> (plasma protein). Transports Cr(III) throughout the body in the blood cells
Copper	<i>Ceruloplasmin</i> (human serum protein), <i>ascorbate oxidase</i> (plants and bacteria), <i>plastocyanin</i> (higher plants and cyanobacteria), <i>superoxide dismutase</i> , <i>tyrosinase</i> , <i>cytocrome oxidase</i> and <i>hemocuprein</i> (animals).
Lead	Around 95% of total Lead in human blood is bound to erythrocytes. In most erythrocytes, the lead is bound within the cell in <i>haemoglobin</i> . In extracellular fluids lead is bound to <i>albumin</i> and some high molecular weight proteins ( <i>globulins</i> ).
Zinc	Zinc is a constituent in more than 200 enzymes and proteins. The principal examples are <i>insulin</i> and <i>carboxypeptidase A</i> .
Manganese	This metal is found in a variety of enzymes such as <i>pyruvate carboxylase</i> and <i>oxalacetate decarboxylase</i> . It can be found in proteins such as <i>glutamine synthetase</i> , <i>β-globulin</i> and <i>albumin</i> .
Iron	Proteins containing iron are classified into two categories. The first is haeme, where this metal is chelated by <i>porphyrin</i> (a water-insoluble ligand). This class is constituted by <i>haemoglobin</i> , <i>myoglobin</i> and <i>cytochromes</i> . The second is formed by non-haeme iron. The principal examples are <i>transferrin</i> , <i>ferritin</i> , <i>ovotransferrin</i> , <i>casein</i> , <i>hemosiderin</i> and <i>albumin</i> .

# DECIPHERING METALLOMICS...

- I) How the element (metal or metalloid) is distributed in cellular compartments of a cell
- II) Its coordination environment; in which biomolecule is complexed or what is the bioligand involved in its complexation
- III) Individual concentrations of the metallic species

# **Classification on the metallomic information**

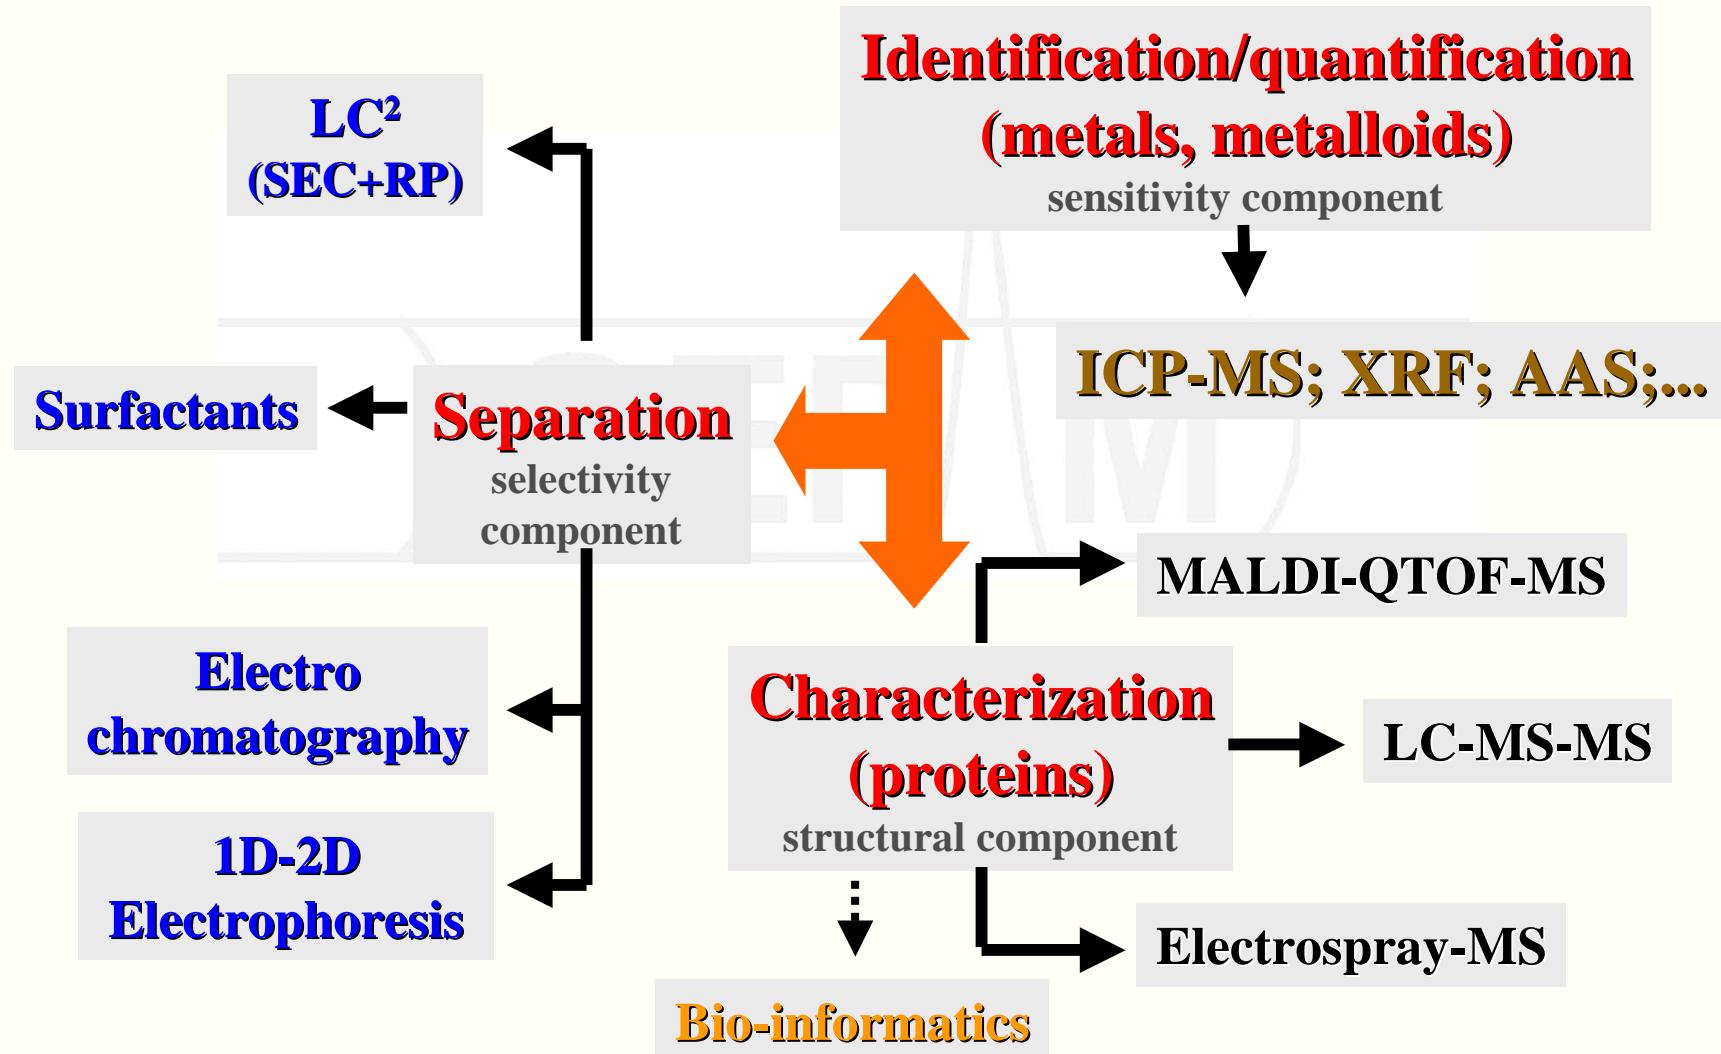

**Qualitative metallomics:** individual species identification

**Quantitative metallomics:** concentration determination of the species

**Comparative metallomics:** monitoring of metallome alterations related to an organism, under influence of external stimulus.

# Strategies on metalloproteomics studies
